1 Advice

Pre-submit:

Are time limits close? If so, generate max cases. Is the memory usage fine? Could anything overflow? Make sure to submit the right file.

Wrong answer: Print your solution! Print debug output, as well. Are you clearing all datastructures between test cases? Can your algorithm handle the whole range of input?

Read the full problem statement again.

Do you handle all corner cases correctly? Have you understood the problem correctly? Any uninitialized variables? Any overflows? Confusing N and M , i and j , etc.? Are you sure your algorithm works? What special cases have you **not** thought of?

Are you sure the STL functions you use work as you think? Add some assertions, maybe resubmit Create some testcases to run your algorithm on. Go through the algorithm **for** a simple **case**.

Go through **this** list again. Explain your algorithm to a team mate. Ask the team mate to look at your code. Go **for** a small walk, e.g. to the toilet. Is your output format correct? Rewrite your solution from the start **or** let a team mate **do** it.

Runtime error: Have you tested all corner cases locally? Any uninitialized variables? Are you reading **or** writing outside the range of any vector? Any assertions that might fail? Any possible division by 0? (mod 0 **for** example). Any possible infinite recursion? Invalidated pointers **or** iterators? Are you **using** too much memory? Debug with resubmits.

Time limit exceeded: Do you have any possible infinite loops? What is the complexity of your algorithm? Are you copying a lot of unnecessary data? (References) How big is the input **and** output? (consider scanf) Avoid vector, map. (use arrays/unordered_map) What **do** your team mates think about your algorithm?

Memory limit exceeded: What is the max amount of memory your algorithm should need? Are you clearing all datastructures between test cases?

Primes - 10001st prime is 1299721, 100001st prime is 15485867 Large primes - 999999937, $1e9+7$, 987646789, 987101789; 78498 primes less than 10^6 The number of divisors of n is at most around 100, **for** $n < 5e4$, 500 **for** $n \leq 1e7$, 2000 **for** $n < 1e10$, 200,000 **for** $n < 1e19$ $7! = 5040$, $8! = 40320$, $9! = 362880$, $10! = 362880$, $11! = 4.0e7$,

$12! = 4.8e8$, $15! = 1.3e12$, $20! = 2e18$

The number of divisors of n is at most around 100 **for** $n < 5e4$, 500 **for** $n < 1e7$, 2000 **for** $n < 1e10$, 200 000 **for** $n < 1e19$.

Articulation points **and** bridges
articulation point:- there exist child : $dfslow[child] \geq dfsnum[curr]$
bridge :- tree ed: $dfslow[ch] > dfsnum[par]$;

A connected multigraph has an Euler path but **not** an Euler circuit **if and only if** it has exactly two vertices of odd degree

Binomial coefficients - base **case** ncn **and** $nc0 = 1$; recursion is $nCk = (n-1)C(k-1) + (n-1)Ck$

Catalan numbers - used in valid paranthesis expressions - formula is $Cn = \sum_{i=0}^{n-1} C_i C_{n-i-1}$; Another formula is $Cn = \frac{2n C_{n-1}}{n+1}$. There are Cn binary trees of n nodes **and** C_{n-1} rooted trees of n nodes

Derangements - $D(n) = (n-1)(D(n-1) + D(n-2))$

Burnsides Lemma - number of equivalence classes = $(\sum I(pi))/n : I(pi)$

are number of fixed points. Usual formula: $\sum_{i=0}^{n-1} k^{\gcd(i,n)} / n$

Stirling numbers - first kind - permutations of n elements with k disjoint cycles. $s(n+1, k) = ns(n, k) + s(n, k-1)$. $s(0, 0) = 1$, $s(n, 0) = 0$ if $n > 0$. $\sum_{k=0}^n s(n, k) = n!$

Stirling numbers - Second kind - partition n objects into k non empty subsets. $S(n+1, k) = kS(n, k) + S(n, k-1)$. $S(0, 0) = 1$, $S(n, 0) = 0$ if $n > 0$. $S(n, k) = (\sum_{j=0}^k (-1)^{k-j} \binom{k}{j} j^n) / k!$

Hermite identity - $\sum_{k=0}^{n-1} \text{floor}[(x+k)/n] = \text{floor}[nx]$

Kirchoff matrix tree theorem - number of spanning trees in a graph is determinant of Laplacian Matrix with one row and column removed, where L = degree matrix - adjacency matrix

Expected value tricks:

1. Linearity of Expectation: $E(X+Y) = E(X) + E(Y)$
2. Contribution to the sum - If we want to find the sum over many ways/possibilities, we should consider every element (maybe a number, or a pair or an edge) and

count how many times it will be added to the answer.

3. For independent events - $E(XY) = E(X)E(Y)$
4. Ordered pairs (Super interpretation of square) - The square of the size of a set is equal to the number of ordered pairs of elements in the set. So we iterate over pairs and for each we compute the contribution to the answer. Similarly, the k -th power is equal to the number of sequences (tuples) of length k .
5. Powers technique - If you want to maintain the sum of k -th powers, it might help to also maintain the sum of smaller powers. For example, if the sum of 0-th, 1-th and 2-nd powers is S_0 , S_1 and S_2 , and we increase every element by x , the new sums are S_0 , $S_1 + S_0x$ and $S_2 + 2S_1x + x^2S_0$.

2 Aho Corasick

```
struct AhoCorasick{
    enum {alpha=26, first='a'};
    struct Node{
        int back, next[alpha], start = -1, end
            = -1, nmatches = 0;
        Node(int
            v){memset(next, v, sizeof(next));};
    }vector<Node> N;
    vector<int> backp;
```

```
inline void insert(string &s, int j){
    assert(!s.empty());
    int n=0;
    for(auto &c: s){
        int &m=N[n].next[c-first];
        if(m==-1){n=m=N.size();
            N.emplace_back(-1);}
        else n=m;
    }
    if(N[n].end==-1) N[n].start=j;
    backp.push_back(N[n].end);
    N[n].end=j;
    N[n].nmatches++;}
void clear(){
    N.clear();
    backp.clear();}
void create(vector<string>& pat){
    N.emplace_back(-1);
    for(int i=0; i<pat.size(); ++i)
        insert(pat[i], i);

```

9 Euler Path

procedure FindEulerPath(V)

1. iterate through all the edges outgoing from vertex V;
remove **this** edge from the graph,
and call FindEulerPath from the
second end of **this** edge;
2. add vertex V to the answer.

10 Extended Euclidean GCD

```

int egcd(int a, int b, int* x, int* y) {
    if (a == 0) {
        *x = 0; *y = 1;
        return b;
    }
    int x1, y1;
    int gcd = egcd(b % a, a, &x1, &y1);
    *x = y1 - (b / a) * x1;
    *y = x1;
    return gcd;
}

```

11 FFT

```

long double pi = acos(-1);
class FFT {
public:
    static void
        reorder(vector<complex<long
double>> &A) {
        ll n = A.size();
        for (int i = 1, j = 0; i < n;
            i++) {
            int bit = n >> 1;
            for (; j & bit; bit >>= 1) {
                j ^= bit;
            }

Gray codes Applications:

1. Gray code of n bits forms a Hamiltonian cycle on a hypercube, where each bit corresponds to one dimension.
2. Gray code can be used to solve the Towers of Hanoi problem. Let n denote number of disks. Start with Gray code of length n which consists of all zeroes (G(0)) and move between consecutive Gray codes (from G(i) to G(i+1)).

Let i-th bit of current Gray code represent n-th disk (the least significant bit corresponds to the smallest disk and the most significant bit to the biggest disk). Since exactly one bit changes on each step, we can treat changing i-th bit as moving i-th disk. Notice that there is exactly one move option for each disk (except the smallest

one) on each step (except start and finish positions).

There are always two move options for the smallest disk but there is a strategy which will always lead to answer:

if n is odd then sequence of the smallest disk moves looks like
 ftrftr ... where f is the initial rod, t is the terminal rod and r is the remaining rod),
 and if n is even:

```

    frtfrt ....
int gray (int n) {return n ^ (n >> 1);}
int rev_g (int g) {
    int n = 0;
    for (; g; g >>= 1) n ^= g;
    return n;}

```

Enumerating all submasks of a bitmask:

```

for (int s=m; ; s=(s-1)&m) {
    ... you can use s ...
    if (s==0) break;}

```

Divide and Conquer DP:

Some dynamic programming problems have a recurrence of this form:

$dp(i,j) = \min_k \{dp(i_1, k) + C(k, j)\}$ where $C(k, j)$ is some cost function.

Say $1 \leq i \leq n$ and $1 \leq j \leq m$, and evaluating C takes $O(1)$ time.

Straightforward evaluation of the above recurrence is $O(nm^2)$.

There are nm states, and m transitions for each state.

Let $opt(i, j)$ be the value of k that minimizes the above expression. If $opt(i, j) \leq opt(i, j+1)$ for all i, j , then we can apply divide-and-conquer DP. This known as the monotonicity condition. The optimal "splitting point" for a fixed i increases as j increases.

```

int m, n;
vector<long long> dp_before(n),
    dp_cur(n);
long long C(int i, int j);

// compute dp_cur[l], ... dp_cur[r]
// (inclusive)
void compute(int l, int r, int optl, int
    optr) {
    if (l > r) return;

    int mid = (l + r) >> 1;
    pair<long long, int> best =
        {LLONG_MAX, -1};

    for (int k = optl; k <= min(mid,
        optr); k++)
        best = min(best, {(k ?
            dp_before[k - 1] : 0) + C(k,
            mid), k});

    dp_cur[mid] = best.first;
    int opt = best.second;

```

```

compute(l, mid - 1, optl, opt);
compute(mid + 1, r, opt, optr);}

```

```

int solve() {
    for (int i = 0; i < n; i++)
        dp_before[i] = C(0, i);
    for (int i = 1; i < m; i++) {
        compute(0, n - 1, 0, n - 1);
        dp_before = dp_cur;
    }
    return dp_before[n - 1];}

```

Knuth Optimization:

```

dp[i][j] = mini < k < j
    {dp[i][k] + dp[k][j]} + C[i][j]
monotonicity : C[b][c] <= C[a][d]
quadrangle inequality: C[a][c]+C[b][d]
    <= C[a][d]+C[b][c]

```

Lyndon factorization: We can get the minimum cyclic shift.

Factorize the string as $s = w_1 w_2 w_3 \dots w_n$

```

string min_cyclic_string(string s) {
    s += s;
    int n = s.size();
    int i = 0, ans = 0;
    while (i < n / 2) {
        ans = i;
        int j = i + 1, k = i;
        while (j < n && s[k] <= s[j]) {
            if (s[k] < s[j])
                k = i;
            else

```

```

        k++;
        j++;}
    while (i <= k)
        i += j - k;}
    return s.substr(ans, n / 2);}

```

Rank of a matrix:

```

const double EPS = 1E-9;
int compute_rank(vector<vector<double>>
    A) {
    int n = A.size();
    int m = A[0].size();
    int rank = 0;
    vector<bool> row_selected(n, false);
    for (int i = 0; i < m; ++i) {
        int j;
        for (j = 0; j < n; ++j) {
            if (!row_selected[j] &&
                abs(A[j][i]) > EPS)
                break;}
        if (j != n) {
            ++rank;
            row_selected[j] = true;
            for (int p = i + 1; p < m;
                ++p)
                A[j][p] /= A[j][i];
            for (int k = 0; k < n; ++k) {
                if (k != j && abs(A[k][i])
                    > EPS) {
                    for (int p = i + 1; p
                        < m; ++p)
                        A[k][p] -= A[j][p]
                            * A[k][i];}}}}
    return rank;}

```

Determinant of a matrix:

```

const double EPS = 1E-9;
int n;
vector < vector<double> > a (n,
    vector<double> (n));
double det = 1;
for (int i=0; i<n; ++i) {
    int k = i;
    for (int j=i+1; j<n; ++j)
        if (abs (a[j][i]) > abs (a[k][i]))
            k = j;
    if (abs (a[k][i]) < EPS) {
        det = 0;
        break;}
    swap (a[i], a[k]);
    if (i != k)
        det = -det;
    det *= a[i][i];
    for (int j=i+1; j<n; ++j)
        a[i][j] /= a[i][i];
    for (int j=0; j<n; ++j)
        if (j != i && abs (a[j][i]) > EPS)
            for (int k=i+1; k<n; ++k)
                a[j][k] -= a[i][k] *
                    a[j][i];}
    cout << det;

```

Generating all k-subsets:

```

vector<int> ans;
void gen(int n, int k, int idx, bool
    rev) {
    if (k > n || k < 0) return;

```

```

    if (!n) {
        for (int i = 0; i < idx; ++i) {
            if (ans[i]) cout << i + 1;}
        cout << "\n";
        return;}
    ans[idx] = rev;
    gen(n - 1, k - rev, idx + 1, false);
    ans[idx] = !rev;
    gen(n - 1, k - !rev, idx + 1, true);}
void all_combinations(int n, int k) {
    ans.resize(n);gen(n, k, 0, false);}

```

Picks theorem:

Given a certain lattice polygon with non-zero area. We denote its area by S , the number of points with integer coordinates lying strictly inside the polygon by I and the number of points lying on polygon sides by B . Then, the Pick formula states: $S = I + B/2 - 1$. In particular, if the values of I and B for a polygon are given, the area can be calculated in $O(1)$ without even knowing the vertices.

Strongly Connected component and Condensation Graph:

```

vector < vector<int> > g, gr;
vector<bool> used;
vector<int> order, component;
void dfs1 (int v) {
    used[v] = true;

```

```

for (size_t i=0; i<g[v].size();
    ++i)
    if (!used[ g[v][i] ]) dfs1
        (g[v][i]);
order.push_back (v);}
void dfs2 (int v) {
    used[v] = true;
    component.push_back (v);
    for (size_t i=0; i<gr[v].size();
        ++i)
        if (!used[ gr[v][i] ]) dfs2
            (gr[v][i]);}
int main() {
    int n;
    ... reading n ...
    for (;;) {
        int a, b;
        ... reading next edge (a,b)
        ...
        g[a].push_back (b);
        gr[b].push_back (a);
    }
    used.assign (n, false);
    for (int i=0; i<n; ++i)
        if (!used[i]) dfs1 (i);
    used.assign (n, false);
    for (int i=0; i<n; ++i) {
        int v = order[n-1-i];
        if (!used[v]) { dfs2 (v);
            ... printing next
                component ...
            component.clear();
        }}}

```

FFT Matrices:

XOR FFT: $1 \ 1 \ / \ 1 \ -1$, AND FFT: $0 \ 1 / \ 1 \ 1$,
OR FFT: $1 \ 1 / \ 1 \ 0$

Standard question: Number of co-prime
integers in range $1, n$

Answer: $f(n) = \sum_{d=1}^n u(d) \text{floor}(n/d)^2$

Euler totient: $\phi(\text{totient fn}) = u * n$
(dirichlet convolution)

a Nim position (n_1, \dots, n_k) is a second
player win in misere Nim if and only
if some $n_i > 1$ and $n_1 \text{ xor } \dots \text{ xor } n_k = 0$,
or all $n_i \leq 1$ and $n_1 \text{ xor } \dots \text{ xor } n_k = 1$.

Fibonacci Identities:

- $F_{n-1}F_{n+1} - F_n^2 = (-1)^n$
- $F_{n+k} = F_k F_{n+1} + F_{k-1} F_n$
- $F_n \mid F_m \Leftrightarrow n \mid m$
- $\text{GCD}(F_m, F_n) = F_{\text{gcd}(m, n)}$
- $F_{2k} = F_k(2F_{k+1} - F_k)$.
 $F_{2k+1} = F_{k+1}^2 + F_k^2$
- $n \geq \phi(m) \Rightarrow x^n = x^{(\phi(m) + n \% \phi(m)) \bmod m}$

Counting labeled graphs:

The total number of labelled graphs is
 $G_n = 2^{\binom{n}{2}}$

Number of connected labelled graphs is
 $C_n = G_n - 1/n * (\sum_{k=1}^{n-1} k \cdot C_k \cdot G_{n-k})$

Number of labelled graphs with k
components: $D[n][k] = \sum_{s=1}^n \binom{n-1}{s-1} C_s D_{n-s}[k-1]$

Sum of subsets DP:

$F(x) = \text{sum of all } A(i) \text{ such that } x \& i = i$.

//iterative version

```

for(int mask = 0; mask < (1<<N); ++mask){
    dp[mask][-1] = A[mask]; //handle base
    case separately (leaf states)
    for(int i = 0; i < N; ++i){
        if(mask & (1<<i))
            dp[mask][i] = dp[mask][i-1] +
                dp[mask^(1<<i)][i-1];
        else
            dp[mask][i] = dp[mask][i-1];}
    F[mask] = dp[mask][N-1];}

```

//memory optimized, super easy to code.

```

for(int i = 0; i < (1<<N); ++i) F[i] =
    A[i];
for(int i = 0; i < N; ++i) for(int mask =
    0; mask < (1<<N); ++mask){
    if(mask & (1<<i)) F[mask] +=
        F[mask^(1<<i)];}

```
